There are $k \ 1 \times 1$ square obstacles on a rectangular $n \times m$ field. A ball starts moving diagonally to axes from a certain point. The ball reflects from the walls. When the ball collides with an obstacle, the latter is destroyed and the ball reflects naturally. Determine the time when the last obstacle is destroyed.

A. Ar	kanoid								

A naive simulating approach can work in O(nmk) time in the worst case.

A						
00000						
A. Ar	kanoic	1				

A naive simulating approach can work in O(nmk) time in the worst case.

The hardest part is to find for a certain ball position and a set of obstacles (some of the initial ones could get destroyed) which obstacle is the next to be destroyed.

A. Arkanoid

Let us number all possible pairs of position and direction of the ball starting from a certain point.

A. Arkanoid

Let us number all possible pairs of position and direction of the ball starting from a certain point.

If one has the number k of the situation (position + direction), one can transform it to actual position and velocity coordinates. Indeed, consider time moment k. If the ball started from (0.5, 0) moving to the upper right, it must have made $\lfloor (0.5k + 0.5)/m \rfloor$ bounces from vertical sides and $\lfloor 0.5k/n \rfloor$ from horizontal sides. This information is enough to find the coordinates and velocity.

A									
00000	0000	000	000	00	000	000	0000	000000	000
A. Ar	kanoid								

To answer a converse question, that is, determine the number k from coordinates and velocity, first notice that the pair (x-coordinate, x-velocity) periodically repeats with period 4m; the same holds for y and period 4n. Thus, one has to solve a system of modular equations of sort:

$$k \equiv k_x \pmod{4m}, k \equiv k_y \pmod{4n},$$

First, suppose that a given digraph is a DAG (*directed acyclic graph*). Can we determine the set of good vertices in this case?

Choose a topological ordering of the DAG arbitrarily. For simplicity we will identify vertices of the DAG with their indices in topsort.

A vertex v is good iff all vertices u > v are reachable from v, and v is reachable from any u < v. We will check the first condition for all vertices; the second one can be checked in a completely symmetrical way.

For a vertex u > v let $deg_+(v|u)$ denote the number of edges (w, u) with $w \ge v$. Let us call a vertex u a v-source if $deg_+(v|u) = 0$ (that is, u is a source in the part of the graph to the right of v including v).

・ロト ・ 理 ト ・ ヨ ト ・ ヨ ト

= 900

B. Vari-directional Streets

For a vertex u > v let $deg_+(v|u)$ denote the number of edges (w, u) with $w \ge v$. Let us call a vertex u a v-source if $deg_+(v|u) = 0$ (that is, u is a source in the part of the graph to the right of v including v).

Note that existence of a vertex u > v that is unreachable from v is equivalent to existence of a *v*-source different from *v*.

B. Vari-directional Streets

For a vertex u > v let $deg_+(v|u)$ denote the number of edges (w, u) with $w \ge v$. Let us call a vertex u a v-source if $deg_+(v|u) = 0$ (that is, u is a source in the part of the graph to the right of v including v).

Note that existence of a vertex u > v that is unreachable from v is equivalent to existence of a *v*-source different from *v*.

Let us iterate over all possible v from left to right, and maintain $deg_+(v|u)$ for all $u \ge v$ along with the number of vertices with $deg_+(v|u) = 0$.

0000

For a vertex u > v let $deg_+(v|u)$ denote the number of edges (w, u) with $w \ge v$. Let us call a vertex u a v-source if $deg_+(v|u) = 0$ (that is, u is a source in the part of the graph to the right of v including v).

Note that existence of a vertex u > v that is unreachable from v is equivalent to existence of a *v*-source different from *v*.

Let us iterate over all possible v from left to right, and maintain $deg_+(v|u)$ for all $u \ge v$ along with the number of vertices with $deg_+(v|u) = 0$.

To move from v to v + 1 simply decrease in-degree of all vertices directly reachable from v.

For a vertex u > v let $deg_+(v|u)$ denote the number of edges (w, u) with $w \ge v$. Let us call a vertex u a v-source if $deg_+(v|u) = 0$ (that is, u is a source in the part of the graph to the right of v including v).

Note that existence of a vertex u > v that is unreachable from v is equivalent to existence of a v-source different from v.

Let us iterate over all possible v from left to right, and maintain $deg_+(v|u)$ for all $u \ge v$ along with the number of vertices with $deg_+(v|u) = 0$.

To move from v to v+1 simply decrease in-degree of all vertices directly reachable from v.

To check the symmetrical condition consider the reversed graph. A vertex v is good if doesn't have a v-source in both cases.

We have to take care not to add the same entry to the structure twice. One way of doing it is to only append the elements that go later in the sequence than the previous last element, hence there is a unique order of adding elements for each subsequence.

Optimization 1: if the size of the structure is greater than k, we can remove the largest entry.

Optimization 2: sort the given numbers (don't forget to store their original indices), stop trying to append a number when the sum becomes too great to fit in the structure.

This approach might still take too long since we have a lot of options to append a number on each step.

・ロト ・ 一下・ ・ モト ・ モト・

D. Ne	cklace					

This approach might still take too long since we have a lot of options to append a number on each step.

Optimization 3: leave only O(1) transitions from each state by introducting new information. Instead of (sum, subset of indices, [possibly lower bound for index]), we will now have (lower bound for sum after adding the number *i*, subset of indices, current position *i*).

While processing the next state we have to try to add number i and add the subset to the list of generated sequences. However, in the sequel we may opt to skip the number. The two transitions are to continue with the number a_i included or not included in the subset; in both cases the current position is increased by 1. Note that the lower bound for the sum does not decrease in any case.

The two transitions are to continue with the number a_i included or not included in the subset; in both cases the current position is increased by 1. Note that the lower bound for the sum does not decrease in any case.

It is easy to see that the target sequence will not have more than $\log_2 k$ elements since all the subsets of a subsequence precede it in the order. Thus the described solution has complexity $O(n \log n + k \log^2 k)$, since we compare two states in $O(\log_2 k)$ time.

Each cycle of the graph lies completely inside of a biconnected component. Consider a separate component.

If the component consists of a single edge, then it contains no cycles.

If the component is a cycle of length I, then we have 2I closed paths for every choice of starting point and direction.

Each cycle of the graph lies completely inside of a biconnected component. Consider a separate component.

If the component consists of a single edge, then it contains no cycles.

If the component is a cycle of length I, then we have 2I closed paths for every choice of starting point and direction.

Otherwise, suppose that all simple cycles contain I edges each. Consider a pair C_1 , C_2 of intersecting cycles, and take their symmetrical difference S (that is, the set of edges that are present in exactly one of the cycles).

Each cycle of the graph lies completely inside of a biconnected component. Consider a separate component.

If the component consists of a single edge, then it contains no cycles.

If the component is a cycle of length *I*, then we have 2*I* closed paths for every choice of starting point and direction.

Otherwise, suppose that all simple cycles contain I edges each. Consider a pair C_1 , C_2 of intersecting cycles, and take their symmetrical difference S (that is, the set of edges that are present in exactly one of the cycles).

The set S has less than 2/ edges, and can be decomposed into simple cycles. By assumption, S must itself be a cycle of length *I*. If that is the case, the intersection of C_1 and C_2 must be a path of length I/2. Thus $C_1 \cup C_2$ is a graph that consists of three edge-disjoint paths of length I/2 between a pair of vertices v and u.

Each cycle of the graph lies completely inside of a biconnected component. Consider a separate component.

If the component consists of a single edge, then it contains no cycles.

If the component is a cycle of length *I*, then we have 2*I* closed paths for every choice of starting point and direction.

Otherwise, suppose that all simple cycles contain I edges each. Consider a pair C_1 , C_2 of intersecting cycles, and take their symmetrical difference S (that is, the set of edges that are present in exactly one of the cycles).

The set S has less than 2/ edges, and can be decomposed into simple cycles. By assumption, S must itself be a cycle of length *I*. If that is the case, the intersection of C_1 and C_2 must be a path of length *I*/2. Thus $C_1 \cup C_2$ is a graph that consists of three edge-disjoint paths of length *I*/2 between a pair of vertices v and u.

Note that no additional edges can be added between vertices of $C_1 \cup C_2$ so that each cycle has length *I*.

If $C_1 \cup C_2$ is not the whole component yet, there must be a cycle that has common edges with C_1 or C_2 , but doesn't lie completely inside $C_1 \cup C_2$. By a similar argument, the new cycle must consist of two paths of length I/2 between v and u: one old and one new.

If $C_1 \cup C_2$ is not the whole component yet, there must be a cycle that has common edges with C_1 or C_2 , but doesn't lie completely inside $C_1 \cup C_2$. By a similar argument, the new cycle must consist of two paths of length I/2 between v and u: one old and one new.

It follows that all simple cycles in a biconnected component have same length iff the component consists of several paths of equal length between a certain pair of vertices.

If $C_1 \cup C_2$ is not the whole component yet, there must be a cycle that has common edges with C_1 or C_2 , but doesn't lie completely inside $C_1 \cup C_2$. By a similar argument, the new cycle must consist of two paths of length I/2 between v and u: one old and one new.

It follows that all simple cycles in a biconnected component have same length iff the component consists of several paths of equal length between a certain pair of vertices.

In case the component is not an edge nor a cycle, these two vertices should be exactly the vertices with degree greater than 2.

If $C_1 \cup C_2$ is not the whole component yet, there must be a cycle that has common edges with C_1 or C_2 , but doesn't lie completely inside $C_1 \cup C_2$. By a similar argument, the new cycle must consist of two paths of length I/2 between v and u: one old and one new.

It follows that all simple cycles in a biconnected component have same length iff the component consists of several paths of equal length between a certain pair of vertices.

In case the component is not an edge nor a cycle, these two vertices should be exactly the vertices with degree greater than 2.

The path structure can be easily found if the component is given.

If $C_1 \cup C_2$ is not the whole component yet, there must be a cycle that has common edges with C_1 or C_2 , but doesn't lie completely inside $C_1 \cup C_2$. By a similar argument, the new cycle must consist of two paths of length I/2 between v and u: one old and one new.

It follows that all simple cycles in a biconnected component have same length iff the component consists of several paths of equal length between a certain pair of vertices.

In case the component is not an edge nor a cycle, these two vertices should be exactly the vertices with degree greater than 2.

The path structure can be easily found if the component is given.

Finally, we can decompose the graph into biconnected components in O(n + m) time. We should also check that the cycle lengths for different components are equal.

G. Pa	rade									

First we solve a "vertical" version of the problem. Make the tree rooted, and let down(v) be the answer if the path goes from v into its subtree, and we only consider the edges in the subtree (no edge from v to the parent). down(v) will allow for a single-vertex path (unlike the original problem).

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

We will have to count several DP's. First is the standard $paths_{v,u,l}$ for the total number of paths of length *l* from *v* to *u*:

$$paths_{v,v,0} = 1$$
 $paths_{v,u,l} = \sum_{w:(v,w) - \text{ an edge}} paths_{w,u,l-1}$

 $paths'_{v,u,l}$ — the number of paths of length *l* from *v* to *u* that contain *v* only as the start. We want to subtract all non-suitable paths from total. Let *l'* be the last moment a bad path passes through *v*. Hence the formula:

$$paths'_{v,u,l} = paths_{v,u,l} - \sum_{l'=1}^{l-1} paths_{v,v,l'} paths'_{v,u,l-l'}$$

H. Messenger

 $cycle'_{v,u,l}$ — the number of paths of length *l* from *v* to *v* avoiding *u*. Let *l'* be the last moment a bad path passes through *u*. Then

$$cycle'_{v,u,l} = dp_{v,v,l} - \sum_{l'=1}^{l-1} dp_{v,u,l'} paths'_{u,v,l-l'}$$

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 のへで
H. Messenger

 $cycle'_{v,u,l}$ — the number of paths of length *l* from *v* to *v* avoiding *u*. Let *l'* be the last moment a bad path passes through *u*. Then

$$cycle'_{v,u,l} = dp_{v,v,l} - \sum_{l'=1}^{l-1} dp_{v,u,l'} paths'_{u,v,l-l'}$$

Finally, $paths''_{v,u,l}$ is the answer to the original problem. In a similar way we have

$$paths_{v,u,l}'' = paths_{v,u,l}' - \sum_{l'=1}^{l-1} paths_{v,u,l'}' cycle_{u,v,l-l'}'$$

H. Messenger

 $cycle'_{v,u,l}$ — the number of paths of length *l* from *v* to *v* avoiding *u*. Let *l'* be the last moment a bad path passes through *u*. Then

$$cycle'_{v,u,l} = dp_{v,v,l} - \sum_{l'=1}^{l-1} dp_{v,u,l'} paths'_{u,v,l-l'}$$

Finally, $paths''_{v,u,l}$ is the answer to the original problem. In a similar way we have

$$paths_{v,u,l}'' = paths_{v,u,l}' - \sum_{l'=1}^{l-1} paths_{v,u,l'}' cycle_{u,v,l-l'}'$$

All the above values can be computed in $O(nml + n^2l^2)$ time, and each query can be answered in O(1) time.

T. Dil	igent.	John	V							

Fact

The minimal number of swaps to change a permutation p into permutation q is equal to n - (number of cycles in $p^{-1}q$).

One can check with some case analysis (or with brute-force for small numbers) that the number of swaps needed to change $(k, n, \ldots, k+1, k-1, \ldots, 1)$ into $(k+1, 1, \ldots, k, k+2, \ldots, n)$ doesn't depend on k and is equal to $\lceil n/2 \rceil$.

00000	0000	0	000	000	00	000	000	0000	000000	000
T. Dil	igent.	John	V							

Fact

The minimal number of swaps to change a permutation p into permutation q is equal to n - (number of cycles in $p^{-1}q$).

One can check with some case analysis (or with brute-force for small numbers) that the number of swaps needed to change $(k, n, \ldots, k+1, k-1, \ldots, 1)$ into $(k+1, 1, \ldots, k, k+2, \ldots, n)$ doesn't depend on k and is equal to $\lceil n/2 \rceil$.

Thus, we have $f(n) = nf(n-1) + (n-1)\lceil n/2\rceil$. Values of this recurrence can readily be found in O(n) time.

Now to solve the "partial" problem: find the number of steps to obtain (p_1, \ldots, p_n) from $(1, \ldots, n)$.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 三臣 - のへで

Now to solve the "partial" problem: find the number of steps to obtain (p_1, \ldots, p_n) from $(1, \ldots, n)$.

Suppose we have just obtained the correct prefix of length l - 1, so all the rest elements p_1, \ldots, p_n are currently in increasing order.

Now to solve the "partial" problem: find the number of steps to obtain (p_1, \ldots, p_n) from $(1, \ldots, n)$.

Suppose we have just obtained the correct prefix of length l - 1, so all the rest elements p_1, \ldots, p_n are currently in increasing order.

Let x_l be the index of p_l among the remaining elements if we order them by increasing. To place p_l in *l*-th position we have to do $x_l - 1$ repetitions of "swap the suffix" and "apply next permutation so that *l*-th element increases".

Now to solve the "partial" problem: find the number of steps to obtain (p_1, \ldots, p_n) from $(1, \ldots, n)$.

Suppose we have just obtained the correct prefix of length l - 1, so all the rest elements p_1, \ldots, p_n are currently in increasing order.

Let x_l be the index of p_l among the remaining elements if we order them by increasing. To place p_l in *l*-th position we have to do $x_l - 1$ repetitions of "swap the suffix" and "apply next permutation so that *l*-th element increases".

By previous arguments, we have to perform $(x_l - 1)(f(n - l) + \lceil (n - l)/2 \rceil)$ swaps. After that, p_l is in its place, and all the later elements are sorted, thus we reduce to a smaller problem.

Now to solve the "partial" problem: find the number of steps to obtain (p_1, \ldots, p_n) from $(1, \ldots, n)$.

Suppose we have just obtained the correct prefix of length l - 1, so all the rest elements p_1, \ldots, p_n are currently in increasing order.

Let x_l be the index of p_l among the remaining elements if we order them by increasing. To place p_l in *l*-th position we have to do $x_l - 1$ repetitions of "swap the suffix" and "apply next permutation so that *l*-th element increases".

By previous arguments, we have to perform $(x_l - 1)(f(n - l) + \lceil (n - l)/2 \rceil)$ swaps. After that, p_l is in its place, and all the later elements are sorted, thus we reduce to a smaller problem.

Values of x_l can be found using any kind of RSQ data structure in $O(n \log n)$.

Two players are playing a game with n pairs of heaps of stones. Initially both heaps in *i*-th pair contain a_i stones. The first player can remove any number of stones from any heap. The second player must move several stones between heaps in some pair. The first player wants to remove all stones in minimal number of moves, while the second player wants to play as long as possible. Find out the number of moves in the game if both play optimally.

We will say that the first player can *snatch* a move if he forces the second player to move in a situation when each pair of heaps is either empty or has $(2^k, 2^k)$ stones for certain integer k (probably different for different pairs).

These are the only situations that help the first player to get under the upper bound F. Indeed, if the second player could skip moves, then F would be the exact number of moves. Thus, the only way to do better than F is to force the second player to do harmful moves.

These are the only situations that help the first player to get under the upper bound F. Indeed, if the second player could skip moves, then F would be the exact number of moves. Thus, the only way to do better than F is to force the second player to do harmful moves.

Note that if some pair contains unequal heaps, than the second player can effectively skip a move, thus such situations are not appealing to the first player.

00000	0000	000	000	00	000	000	0000	000000	000
J. No	t Nim								

Suppose that the first player will move in a pair that currently contains (x, x) stones. Forcing a second player's move here will result in (x - 1, 0) instead of (x, 0) (if the second player could skip). The move will be harmful if $\lfloor \log_2(x - 1) \rfloor < \lfloor \log_2 x \rfloor$, or, equivalently, $x = 2^k$.

00000	0000	000	000	00	000	000	0000	000000	000
J. No	t Nim								

Suppose that the first player will move in a pair that currently contains (x, x) stones. Forcing a second player's move here will result in (x - 1, 0) instead of (x, 0) (if the second player could skip). The move will be harmful if $\lfloor \log_2(x - 1) \rfloor < \lfloor \log_2 x \rfloor$, or, equivalently, $x = 2^k$.

Since all $(2^k, 2^k)$ pairs can be forced into (1, 1) pairs, the first player wants to force situations when all pairs are (1, 1) or empty.

Suppose that the first player will move in a pair that currently contains (x, x) stones. Forcing a second player's move here will result in (x - 1, 0) instead of (x, 0) (if the second player could skip). The move will be harmful if $\lfloor \log_2(x - 1) \rfloor < \lfloor \log_2 x \rfloor$, or, equivalently, $x = 2^k$.

Since all $(2^k, 2^k)$ pairs can be forced into (1, 1) pairs, the first player wants to force situations when all pairs are (1, 1) or empty.

Forcing of a move happens when the first player empties the last heap in some pair. When this happens, we want all other pairs to contain equal heaps (otherwise, the second player can effectively skip).

Suppose that the first player will move in a pair that currently contains (x, x) stones. Forcing a second player's move here will result in (x - 1, 0) instead of (x, 0) (if the second player could skip). The move will be harmful if $\lfloor \log_2(x - 1) \rfloor < \lfloor \log_2 x \rfloor$, or, equivalently, $x = 2^k$.

Since all $(2^k, 2^k)$ pairs can be forced into (1, 1) pairs, the first player wants to force situations when all pairs are (1, 1) or empty.

Forcing of a move happens when the first player empties the last heap in some pair. When this happens, we want all other pairs to contain equal heaps (otherwise, the second player can effectively skip).

We want to make sizes of all pairs as close to (1, 1) as possible without making unequal pairs. By making enough moves, a pair (x, x) can be forced to a pair $(2^k - 1, 2^k - 1)$, where k is the number of leading ones in binary representation of x. Moving further in this pair will result in unequal heaps. We suppose that at all times the heaps are reduced to this form.

Suppose that the second player moves in a $(2^k - 1, 2^k - 1)$ pair. If k = 0, then we empty the pair and the forcing continues. Otherwise, after dividing by two the heap turns into $(2^{k-1} - 1, 2^{k-1} - 1)$.

▲ロト ▲帰ト ▲ヨト ▲ヨト 三日 - の々ぐ

Suppose that the second player moves in a $(2^k - 1, 2^k - 1)$ pair. If k = 0, then we empty the pair and the forcing continues. Otherwise, after dividing by two the heap turns into $(2^{k-1} - 1, 2^{k-1} - 1)$.

On his move the first player has to choose $(2^k - 1, 2^k - 1)$ pair and empty it. At the end of this pair, the second player is then forced to make a move in another pair.

Suppose that the second player moves in a $(2^k - 1, 2^k - 1)$ pair. If k = 0, then we empty the pair and the forcing continues. Otherwise, after dividing by two the heap turns into $(2^{k-1} - 1, 2^{k-1} - 1)$.

On his move the first player has to choose $(2^k - 1, 2^k - 1)$ pair and empty it. At the end of this pair, the second player is then forced to make a move in another pair.

Observation

Both the first and the second player will choose a pair with maximal k.

Suppose that the second player moves in a $(2^k - 1, 2^k - 1)$ pair. If k = 0, then we empty the pair and the forcing continues. Otherwise, after dividing by two the heap turns into $(2^{k-1} - 1, 2^{k-1} - 1)$.

On his move the first player has to choose $(2^k - 1, 2^k - 1)$ pair and empty it. At the end of this pair, the second player is then forced to make a move in another pair.

Observation

Both the first and the second player will choose a pair with maximal k.

Indeed, the first player will want the second player to move in small pairs, so he'll eliminate the large ones.

Suppose that the second player moves in a $(2^k - 1, 2^k - 1)$ pair. If k = 0, then we empty the pair and the forcing continues. Otherwise, after dividing by two the heap turns into $(2^{k-1} - 1, 2^{k-1} - 1)$.

On his move the first player has to choose $(2^k - 1, 2^k - 1)$ pair and empty it. At the end of this pair, the second player is then forced to make a move in another pair.

Observation

Both the first and the second player will choose a pair with maximal k.

Indeed, the first player will want the second player to move in small pairs, so he'll eliminate the large ones.

Similarly, in the end the second player wants to have as few (1,1) pairs as possible, so he'll avoid making them from (3,3). Similarly, to avoid making (3,3) he'll avoid moving in (7,7), and so on.

00000	0000	000	000	00	000	000	0000	000000	000
J. No	t Nim								

Finally, we can model the game as follows. After reducing all heaps to $(2^k - 1, 2^k - 1)$ form we'll store the number of pairs with $k = 0, 1, \dots, \log_2 A$ (where A is the maximal value of a heap size).

Finally, we can model the game as follows. After reducing all heaps to $(2^k - 1, 2^k - 1)$ form we'll store the number of pairs with $k = 0, 1, \dots, \log_2 A$ (where A is the maximal value of a heap size).

The first player will choose k as large as possible and erase one $(2^k - 1)$ -pair. Then the second player chooses the largest possible pair too.
Finally, we can model the game as follows. After reducing all heaps to $(2^k - 1, 2^k - 1)$ form we'll store the number of pairs with $k = 0, 1, \dots, \log_2 A$ (where A is the maximal value of a heap size).

The first player will choose k as large as possible and erase one $(2^k - 1)$ -pair. Then the second player chooses the largest possible pair too.

If he has k > 0, then he turns this pair into $(2^{k-1} - 1)$ and the first player moves again.

Finally, we can model the game as follows. After reducing all heaps to $(2^k - 1, 2^k - 1)$ form we'll store the number of pairs with $k = 0, 1, \dots, \log_2 A$ (where A is the maximal value of a heap size).

The first player will choose k as large as possible and erase one $(2^k - 1)$ -pair. Then the second player chooses the largest possible pair too.

If he has k > 0, then he turns this pair into $(2^{k-1} - 1)$ and the first player moves again.

Otherwise, all the rest moves of the second player are forced.

Finally, we can model the game as follows. After reducing all heaps to $(2^k - 1, 2^k - 1)$ form we'll store the number of pairs with $k = 0, 1, ..., \log_2 A$ (where A is the maximal value of a heap size).

The first player will choose k as large as possible and erase one $(2^k - 1)$ -pair. Then the second player chooses the largest possible pair too.

If he has k > 0, then he turns this pair into $(2^{k-1} - 1)$ and the first player moves again.

Otherwise, all the rest moves of the second player are forced.

All preprocessing and the final game process can be implemented in $O(n \log A)$ time.

Finally, we can model the game as follows. After reducing all heaps to $(2^k - 1, 2^k - 1)$ form we'll store the number of pairs with $k = 0, 1, \dots, \log_2 A$ (where A is the maximal value of a heap size).

The first player will choose k as large as possible and erase one $(2^k - 1)$ -pair. Then the second player chooses the largest possible pair too.

If he has k > 0, then he turns this pair into $(2^{k-1} - 1)$ and the first player moves again.

Otherwise, all the rest moves of the second player are forced.

All preprocessing and the final game process can be implemented in $O(n \log A)$ time.

If you have trouble understanding this solution, try to work out why the answer for 3, 3, 3 input is 15 instead of 17.

where *i* ranges over all processed rows.

									к
00000	0000	000	000	00	000	000	0000	000000	000
K. St	utter								

Let us compute $dp_{i,j}$ row by row. We can't store the whole matrix, so we'll just have two last rows.

To account for $dp_{prev(...),prev(...)}$ let us store

$$dp_j^{equal} = \max_{i|a_i=b_j} dp_{i-1,j-1},$$

where *i* ranges over all processed rows.

Note that we can use $dp_{prev(b,j,c)}^{equal}$ in place of $dp_{prev(a,i,c)-1,prev(b,j,c)-1}$. This eliminates our need for $\Omega(nm)$ memory and requires only O(n+m) memory.
