A cylinder is flying in 3D space with an initial velocity under constant acceleration force. The axis of the cylinder is always aligned with the speed vector. Determine if the cylinder will ever hit a given point q.

Outline: reduce to a 2D problem, solve some polynomial inequalities.

A										
0000		000	00	00000	00	000	00	000	00	000
A. Ha	anso	vs Ge	nji							

Let v be the initial speed vector, and g be the gravitational force. Consider π — the plane containing the initial position of mass center, and parallel to v and g. Clearly, the mass center will always stay inside this plane. It is also evident that the distance from any fixed point of the cylinder to this plane will remain constant.

A. Ha	anso	vs Ge	nji							

Let v be the initial speed vector, and g be the gravitational force. Consider π — the plane containing the initial position of mass center, and parallel to v and g. Clearly, the mass center will always stay inside this plane. It is also evident that the distance from any fixed point of the cylinder to this plane will remain constant.

Let us cut the cylinder with a plane parallel to π that passes through q. The intersection is either empty or a rectangle. It is this rectangle that has the change to hit the point q. Also note that it behaves like a full 2D analogue of the cylinder (if we take its center to be the mass center). We can thus reduce to a 2D version of the problem. Introduce a 2D coordinate system in a suitable way.

A 000C

> Let the center mass move according to the rule $p(x) = (x, v_y x - gx^2/2)$, the speed vector is then equal to $v(x) = (1, v_y - gx)$. Also let $u(x) = (v_y - gx, -1)$ be the vector orthogonal to v.

> Assume that the rectangle's speed-aligned side's length is equal to L, and the orthogonal side's length is equal to W.

A

Let the center mass move according to the rule $p(x) = (x, v_y x - gx^2/2)$, the speed vector is then equal to $v(x) = (1, v_y - gx)$. Also let $u(x) = (v_y - gx, -1)$ be the vector orthogonal to v.

Assume that the rectangle's speed-aligned side's length is equal to L, and the orthogonal side's length is equal to W.

The rectangle contains a point q at time moment x iff

$$\left|\left(q-p(x),\frac{v(x)}{|v(x)|}\right)\right| \leq L, \left|\left(q-p(x),\frac{u(x)}{|u(x)|}\right)\right| \leq W.$$

Here (\cdot, \cdot) stands for dot product.

A

Assume that the rectangle's speed-aligned side's length is equal to L, and the orthogonal side's length is equal to W.

The rectangle contains a point q at time moment x iff

$$\left|\left(q-p(x),\frac{v(x)}{|v(x)|}\right)\right| \leq L, \left|\left(q-p(x),\frac{u(x)}{|u(x)|}\right)\right| \leq W.$$

Here (\cdot, \cdot) stands for dot product.

Consider the first inequality (the second is almost analogous). After squaring we obtain an equivalent form:

$$(q-p(x),v(x))^2 \leq L^2|v(x)|^2.$$

All vector coordinates are polynomials in x. It can be checked that this is a polynomial inequality of degree 6.

How does one find the solution domain of an arbitrary polynomial inequality? We will describe a method for finding roots of an arbitrary polynomial; the method can be upgraded for finding the domain too.

How does one find the solution domain of an arbitrary polynomial inequality? We will describe a method for finding roots of an arbitrary polynomial; the method can be upgraded for finding the domain too.

Let us have P(x) = 0.

How does one find the solution domain of an arbitrary polynomial inequality? We will describe a method for finding roots of an arbitrary polynomial; the method can be upgraded for finding the domain too.

Let us have P(x) = 0.

Recursively solve for P'(x) = 0, where P' is a formal derivative of P. There is at most one root of P between two consecutive roots of P', use binary search to find or discard them.

An algorithm for checking if all *substrings* of t are greater than corresponding prefixes of s:

An algorithm for checking if all *substrings* of t are greater than corresponding prefixes of s:

• For current position *i* store maximal *l* such that t[i - l + 1..i] = s[1..i].

C. Rotate string

An algorithm for checking if all *substrings* of t are greater than corresponding prefixes of s:

- For current position *i* store maximal *l* such that t[i l + 1..i] = s[1..i].
- To append a single character *c*, repeatedly apply prefix-function of *s* to *i*. On each iteration ensure that continuation of the substring that matches until *i* does not fall under the prefix of *s*.

C. Rotate string

An algorithm for checking if all *substrings* of t are greater than corresponding prefixes of s:

- For current position *i* store maximal *l* such that t[i l + 1..i] = s[1..i].
- To append a single character *c*, repeatedly apply prefix-function of *s* to *i*. On each iteration ensure that continuation of the substring that matches until *i* does not fall under the prefix of *s*.

How do we apply this idea to check the same property for cyclic shifts? The only difference is that now we assume that at the start I is the maximal suffix of t that matches prefix of s. In the end I has to come to its original value.

Let's first solve the problem if the graph is a tree.

For a particular pair of start and finish vertex v, u the answer is at least 2(n-1) - d(v, u), where d(v, u) is the distance between v and u.

・ロト ・ 理 ト ・ ヨ ト ・ ヨ ト

э.

Let's first solve the problem if the graph is a tree.

For a particular pair of start and finish vertex v, u the answer is at least 2(n-1) - d(v, u), where d(v, u) is the distance between v and u.

Indeed, if an edge doesn't lie on the shortest v - u path, we have to traverse it at least twice since we have to visit vertices on the other side, but both v and u lie on the same side of the edge so we have to return.

Let's first solve the problem if the graph is a tree.

0000

For a particular pair of start and finish vertex v, u the answer is at least 2(n-1) - d(v, u), where d(v, u) is the distance between v and u.

Indeed, if an edge doesn't lie on the shortest v - u path, we have to traverse it at least twice since we have to visit vertices on the other side, but both v and u lie on the same side of the edge so we have to return.

If the edge lies on the v - u path, we have to traverse it at least once to get from v to u.

Let's first solve the problem if the graph is a tree.

0000

For a particular pair of start and finish vertex v, u the answer is at least 2(n-1) - d(v, u), where d(v, u) is the distance between v and u.

Indeed, if an edge doesn't lie on the shortest v - u path, we have to traverse it at least twice since we have to visit vertices on the other side, but both v and u lie on the same side of the edge so we have to return.

If the edge lies on the v - u path, we have to traverse it at least once to get from v to u.

This length is attained on a "partial" Euler tour of the tree, so this must be the answer for the choice of v and u.

Let's first solve the problem if the graph is a tree.

0000

For a particular pair of start and finish vertex v, u the answer is at least 2(n-1) - d(v, u), where d(v, u) is the distance between v and u.

Indeed, if an edge doesn't lie on the shortest v - u path, we have to traverse it at least twice since we have to visit vertices on the other side, but both v and u lie on the same side of the edge so we have to return.

If the edge lies on the v - u path, we have to traverse it at least once to get from v to u.

This length is attained on a "partial" Euler tour of the tree, so this must be the answer for the choice of v and u.

To optimize the length, we have to choose v and u as endpoints of a diameter of the tree.

In the actual problem we have a graph that consists of exactly one cycle with some trees hanging from each cycle vertex.

▲ロト ▲御 ト ▲ 臣 ト ▲ 臣 ト の Q @

In the actual problem we have a graph that consists of exactly one cycle with some trees hanging from each cycle vertex.

It doesn't make sense to travel each edge of the cycle. Actually, it does when we start in a subtree, rise up to the cycle, make a whole loop visiting all subtrees while we go, and then return to the same subtree we started. All these options can be accounted for in linear time, and all the other routes do not need to visit all cycle edges indeed. With this observation we can obtain an easy solution: first find the cycle in the graph, then try to erase each edge of the cycle and apply the solution to the remaining tree. There could be $\sim n$ options to try though.

Denote v_1, \ldots, v_k be the vertices of the cycle in order. Consider a tree that hangs on v_i . Let it have the diameter d_i and the longest path down from the root v_i have length l_i .

E

Denote v_1, \ldots, v_k be the vertices of the cycle in order. Consider a tree that hangs on v_i . Let it have the diameter d_i and the longest path down from the root v_i have length l_i .

If we cut the (v_k, v_1) edge, the diameter of the resulting tree is

$$\max\left(\max_{i=1}^{k} d_{i}, \max_{1 \leq i < j \leq k} l_{i} + j - i + l_{j}\right)$$

The second part of the expression corresponds to all options to draw a path between different trees.

Denote v_1, \ldots, v_k be the vertices of the cycle in order. Consider a tree that hangs on v_i . Let it have the diameter d_i and the longest path down from the root v_i have length l_i .

If we cut the (v_k, v_1) edge, the diameter of the resulting tree is

00000

$$\max\left(\max_{i=1}^{k} d_{i}, \max_{1 \leq i < j \leq k} l_{i} + j - i + l_{j}\right)$$

The second part of the expression corresponds to all options to draw a path between different trees.

Note that this expression can be computed in O(n) time. To find the second part, we have to try all j and choose i < j that maximizes $l_i - i$.

Denote v_1, \ldots, v_k be the vertices of the cycle in order. Consider a tree that hangs on v_i . Let it have the diameter d_i and the longest path down from the root v_i have length l_i .

If we cut the (v_k, v_1) edge, the diameter of the resulting tree is

00000

$$\max\left(\max_{i=1}^{k} d_{i}, \max_{1 \leq i < j \leq k} l_{i} + j - i + l_{j}\right)$$

The second part of the expression corresponds to all options to draw a path between different trees.

Note that this expression can be computed in O(n) time. To find the second part, we have to try all j and choose i < j that maximizes $l_i - i$.

To do that fast we store the maximal value of $l_i - i$ over all processed j.

How to account for all possible ways to erase an edge? Let us double the array l_i , that is, append the same elements at the end: $(l_1, \ldots, l_k, l_1, \ldots, l_k)$.

How to account for all possible ways to erase an edge? Let us double the array l_i , that is, append the same elements at the end: $(l_1, \ldots, l_k, l_1, \ldots, l_k)$.

The new array of length 2k contains all cyclic shifts of the original array.

How to account for all possible ways to erase an edge? Let us double the array l_i , that is, append the same elements at the end: $(l_1, \ldots, l_k, l_1, \ldots, l_k)$.

0000

The new array of length 2k contains all cyclic shifts of the original array.

The maximal diameter of all possible trees is now either the maximal d_i for a certain *i* or $l_j + j + l_i - i$ for a certain pair $1 \le i < j \le 2k$ that satisfies j - i < n.

How to account for all possible ways to erase an edge? Let us double the array l_i , that is, append the same elements at the end: $(l_1, \ldots, l_k, l_1, \ldots, l_k)$.

0000

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

We want to subtract the largest palindrome not exceeding n.

We want to subtract the largest palindrome not exceeding n.

Let us suppose that the length of *n* is *l*. We will build *m* as follows: take $l' = \lfloor l/2 \rfloor$ first digits of *n* and add the rest so that *m* has *l* digits and is a palindrome.

J. Ugly Problem

We want to subtract the largest palindrome not exceeding n.

Let us suppose that the length of *n* is *l*. We will build *m* as follows: take $l' = \lfloor l/2 \rfloor$ first digits of *n* and add the rest so that *m* has *l* digits and is a palindrome.

If m > n, subtract 1 from the number formed by the l' largest digits of m and mirror the number again; the new number is less than n. Now we can subtract m from n.

J. Ugly Problem

We want to subtract the largest palindrome not exceeding n.

Let us suppose that the length of *n* is *l*. We will build *m* as follows: take $l' = \lfloor l/2 \rfloor$ first digits of *n* and add the rest so that *m* has *l* digits and is a palindrome.

If m > n, subtract 1 from the number formed by the l' largest digits of m and mirror the number again; the new number is less than n. Now we can subtract m from n.

The special case is when $n = 10^k$, then we need to take $m = 10^k - 1$.

J. Ugly Problem

We want to subtract the largest palindrome not exceeding n.

Let us suppose that the length of *n* is *l*. We will build *m* as follows: take $l' = \lfloor l/2 \rfloor$ first digits of *n* and add the rest so that *m* has *l* digits and is a palindrome.

If m > n, subtract 1 from the number formed by the l' largest digits of m and mirror the number again; the new number is less than n. Now we can subtract m from n.

The special case is when $n = 10^k$, then we need to take $m = 10^k - 1$.

If we don't need to alter *m* after making the first part equal, then $n - m < 10^{l'}$. In the other case, $n - m < 2 \cdot 10^{l'}$. In any case, then length of *n* is roughly halved after every operation, resulting in $O(\log n)$ summands.

										к

Count the total number of elements the BIT (Fenwick tree, etc.) performs for operations "change array elements at positions l and r" pairs (l, r) such that $0 \le l < r \le n$.

Outline: look at binary representation of I and r, express the answer and find it combinatorially/with bitwise DP.

The operation i = i -= i & (-i) effectively wipes the smallest bit of *i* set to 1.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ □臣 = のへで

The operation i = i -= i & (-i) effectively wipes the smallest bit of *i* set to 1.

Let us call a number i a *prefix* of number j if i can be obtained from j using one or several operations described above. For a pair of numbers l and r the number of changed elements is the number of prefixes of l that are not prefixes of r, plus the symmetrical value.

The operation i = i -= i & (-i) effectively wipes the smallest bit of *i* set to 1.

Let us call a number i a *prefix* of number j if i can be obtained from j using one or several operations described above. For a pair of numbers l and r the number of changed elements is the number of prefixes of l that are not prefixes of r, plus the symmetrical value.

A different way to express the answer: for each number x from 1 to n denote f(x) the number of pairs (a, b) with $0 \le a, b \le n$ such that x is a prefix of a but not a prefix of b. Observe that $\sum_{x=1}^{n} f(x)$ differs from the actual answer only in the order of summation.

Further, let g(x) denote the number of y's not exceeding n such that x is a prefix of y, then f(x) = g(x)(n+1-g(x)).

イロト 不得 トイヨト イヨト

э.

Further, let g(x) denote the number of y's not exceeding n such that x is a prefix of y, then f(x) = g(x)(n+1-g(x)).

If k(x) is the number of trailing zeros in binary representation of x, then g(x) = n - x + 1 if x is prefix of n, and $2^{k(x)}$ otherwise.

Further, let g(x) denote the number of y's not exceeding n such that x is a prefix of y, then f(x) = g(x)(n+1-g(x)).

000

If k(x) is the number of trailing zeros in binary representation of x, then g(x) = n - x + 1 if x is prefix of n, and $2^{k(x)}$ otherwise.

For example, let $n = 13 = 1101_2$. Then $g(4) = g(100_2) = 4 = |\{100_2, 101_2, 110_2, 111_2\}|$, but $g(8) = g(1000_2) = 6 = |\{1000_2, 1001_2, 1010_2, 1011_2, 1100_2, 1101_2\}|$.

Further, let g(x) denote the number of y's not exceeding n such that x is a prefix of y, then f(x) = g(x)(n+1-g(x)).

000

If k(x) is the number of trailing zeros in binary representation of x, then g(x) = n - x + 1 if x is prefix of n, and $2^{k(x)}$ otherwise.

For example, let $n = 13 = 1101_2$. Then $g(4) = g(100_2) = 4 = |\{100_2, 101_2, 110_2, 111_2\}|$, but $g(8) = g(1000_2) = 6 = |\{1000_2, 1001_2, 1010_2, 1011_2, 1100_2, 1101_2\}|$.

The number of x's with k(x) = t is $\lfloor (n+2^t)/2^{t+1} \rfloor$, since each of them is $(2z+1)2^t$ for a non-negative integer z.

Further, let g(x) denote the number of y's not exceeding n such that x is a prefix of y, then f(x) = g(x)(n+1-g(x)).

If k(x) is the number of trailing zeros in binary representation of x, then g(x) = n - x + 1 if x is prefix of n, and $2^{k(x)}$ otherwise.

For example, let $n = 13 = 1101_2$. Then $g(4) = g(100_2) = 4 = |\{100_2, 101_2, 110_2, 111_2\}|$, but $g(8) = g(1000_2) = 6 = |\{1000_2, 1001_2, 1010_2, 1011_2, 1100_2, 1101_2\}|$.

The number of x's with k(x) = t is $\lfloor (n+2^t)/2^{t+1} \rfloor$, since each of them is $(2z+1)2^t$ for a non-negative integer z.

Each of these numbers contributes $2^t(n+1-2^t)$ to the answer unless it is a prefix of *n*. All these cases can be handled and summed up in $O(\log n)$.

Further, let g(x) denote the number of y's not exceeding n such that x is a prefix of y, then f(x) = g(x)(n+1-g(x)).

Each of these numbers contributes $2^t(n+1-2^t)$ to the answer unless it is a prefix of *n*. All these cases can be handled and summed up in $O(\log n)$.

Another way to deal with bit manipulations and counting is to implement some king of bitwise DP to count the same or a similar quantities.
